Cell proliferation is a tightly organized process that involves cell division and cell growth, where cell division can be divided into distinct cell cycle phases: G<sub>0</sub>, G<sub>1</sub>, S, G<sub>2</sub>, and M. Transitions through the phases are regulated by several layers of checkpoints and control mechanisms (Baserga, 1981; Lubischer, 2007; Bertoli et al., 2013; Grant et al., 2013).

“Dividing cells pass through a regular sequence of cell growth and division, known as the cell cycle”™, according to a college textbook of biology published in 1983 [1][1], 5 years before the underlying principles of control were first laid bare during 1988, the annus mirabilis of cell cycle

Normal cell cycle Inherent to cytokinetic principles is the concept of the cell cycle. Daughter cells formed as a result of mitosis consist of three subpopulations: (1) cells that are nondividing and terminally differentiated, (2) cells that are continually pro-liferating, and (3) cells that are resting but may be recruited into the cell cycle
